

Orientation changer for parts

Usage A mechanism that changes the orientation of inspected parts.

Explanation When using an air cylinder, the turning unit may turn too fast, sometimes causing the parts held to fall off, and there was a certain lag between the time an order is given and when it actually starts to move. The Elecyylinder has a shorter lag while featuring a smooth acceleration and deceleration, preventing the parts from falling off, resulting in a shorter time to complete its operation (dropped from 2.5 seconds down to 0.3 seconds).
