

# Applying Adhesive to Machine Parts

**Usage** A device that applies adhesive to machine parts using a dispenser.  
A semi-automatic device that moves the dispenser left and right through operation switch.

**Explanation** When an air cylinder was used, there was unevenness in the coating amount due to variations in speed caused by fluctuations in the source pressure.

The adoption of the Elecylinder has made it possible to set the speed simply by entering numerical values, making it possible to achieve a uniform coating amount.

Since no air is used, peripheral equipments such as compressors are no more required, making the device simple and allowing it to operate silently.
